INTERVIEW | Why not, indeed? Two Yale professors propose unconventional solutions to some of life's peskiest problems.

Ian Ayres is co-author, with fellow Yale professor Barry Nalebuff, of *Why Not? How to Use Everyday Ingenuity to Solve Problems Big and Small*.

Among other ideas, you've suggested an alternative to the national Do-Not-Call list. Tell us about it. Telemarketers could call you from a reverse-900 number, and you would get paid to listen to a telemarketer's pitch. While they're trying to sell you a product, you're selling them your time.

How much would people have to be paid to accept a call? I imagine there's an equilibrium price that's about double the minimum wage. But you could charge different prices for different times of day or different types of calls. You could hit *7 if you want to be paid more in the future, or *6 to waive the fee for a charity.

Could such a system work with spam? Sure. Your in-box could be set up to accept only junk e-mails that offer to pay you, say, a nickel to read each of them. If you click on a chit icon, the payment could go into a PayPal or similar account.

What are some of your favorite ideas in the book? One is a fixed-rate mortgage that automatically refinances when rates drop. You might be willing to pay a slightly higher interest rate to save the hassle of refinancing.

Another idea is an adjustable-term mortgage. With adjustable-rate loans, you worry about paying more when rates head up. But what if, instead of payments rising, the loan term were to go from, say, ten years to 12 years? Mortgage markets are so inefficient that they're ripe for ideas.

How can Kiplinger's readers send their innovative ideas to you? They can go to our Web site, at www.whynot.net. I get a lot of hope and inspiration from ideas that people share spontaneously.

Abstract (Document Summary)

This column will be a gathering place for unconventional ideas for products and services. Here is the first: Mortgages that automatically refinance themselves when interest rates fall a percentage point. There is no reason why title insurers, lawyers and appraisers need to collect their toll when interest rates fluctuate. There are a lot more business product ideas where this one came from, and readers are invited to contribute as well. This column will tap into a rather old-fashioned kind of American ingenuity. High-tech breakthroughs are great, but this column will showcase simple ideas, ones that could have - and perhaps should have - already been tried.

Full Text (797 words)

"Some men see things the way they are and say, 'Why?' I dream of things the way they never were and say, 'Why not?'"

--Robert F. Kennedy, after George Bernard Shaw

Robert F. Kennedy challenged us to reject the status quo and give space to our imagination. Why not apply his vision to business? This column will be a gathering place for unconventional ideas for products and services. Here's our first: Why not have mortgages that automatically refinance themselves when interest rates fall a percentage point? There is no reason why title insurers, lawyers and appraisers need to collect their toll when interest rates fluctuate. The bank could split the savings with you, charging, say, \$1,000 for the refinancing but saving you \$2,000 in closing costs. How about it, Citigroup? A small San Diego outfit called City Line Mortgage Corp. already has in place a system for speeding up refinancing paperwork; now all it needs to do is to cut out some of those middlemen.

We have a lot more business product ideas where this one came from, and we want you, the reader, to contribute as well. In this column we will tap into a rather old-fashioned kind of American ingenuity. High-tech breakthroughs are great, but we want to showcase simple ideas, ones that could have--and perhaps should have- -already been tried.

This kind of problem-solving doesn't require an advanced degree. Many people have simple ideas to improve business processes and services. Think about prewashed lettuce, the ultimate low-tech invention, which has become a billion-dollar business. Or inflation- indexed government bonds, an innovation introduced just a decade ago.

And there are plenty more like these just waiting to be given a chance. For example:

Why not have firms call you back rather than have you wait on hold?

Abstract (Document Summary)

-- Intermediaries suddenly have a new service to sell. "Sign up with Verizon and choose your own price for receiving promo calls." Just as Verizon makes money by selling its 900 service, it could charge telemarketers to connect calls for a kind of reverse 900 service that compensates the household for listening.

-- But would telemarketers ever be willing to pay for your time? Of course they would, that's what advertising is. A full page print ad in The Wall Street Journal, for instance, costs \$180,000 or 10 cents a reader. Firms are willing to pay dearly for the chance to get their message to you. And telemarketers would pay here only for the targets they reach. If they don't think the person is listening, they can hang up and stop paying. (Consumers are equally free to quit the call and stop getting paid).

The appropriate role for government is not to tell us what type of calls we can and cannot block. Instead, the "do not call" regulations should simply protect families' right to control whether their phone rings. The current regulation is an important step in this direction. But Congress should allow the market to do more of the work. All that the FTC (or Congress) needs to do is to allow registered households to authorize intermediaries to connect calls that meet their conditions. This can be done by adding 21 words to the current regulation: "A 'specific seller' for purposes of (section) 310.4(b)(1)(iii) shall include intermediaries who are authorized to connect calls that meet pre-specified household prerequisites."

Full Text (855 words)

Copyright (c) 2003, Dow Jones & Company, Inc.

The national Do Not Call Registry is the most popular consumer- protection initiative in our nation's history -- because it makes clear that you "own" the right to be left alone.

But the current law is flawed on two counts. Households can block commercial telemarketers, but not annoying calls from the benevolent association of retired dogcatchers. This government discrimination in favor of charities is why a federal court struck down the regulations as unconstitutional.

More importantly, it misses a market opportunity. The classic role of government is to establish a system of property rights and then to get out of the way to let entitlement flow to highest valuers. But the Do Not Call registry needlessly prevents you from selling a scarce resource -- your time and attention. Telemarketers could call from a reverse 900 number. That way, you would get paid for taking the call. While they are trying to sell you a product, you can be selling them your time.

The FTC can solve the constitutionality issue and create a market by simply tweaking the current regulation.

First, the registry's coverage should be expanded to block calls from any telemarketer that makes more than 100 unsolicited calls a day. This would solve the constitutional difficulty, because the regulation would not turn on the content of the call but on the manner of calling.

Then, households that sign up for the Do Not Call registry should have the right to authorize their phone company to connect any calls that meet the household's price. Just think of it: You could charge different prices for different times of day or for different types of calls. You could even be given the option of hitting a button to waive the compensation -- because you felt that a particular charitable pitch was particularly worthy -- or let through any calls approved by Rush Limbaugh.

Just as Priceline turned the tables on airline pricing, this concept turns the tables on advertising. You tell your phone company your price for listening, and prospective callers can then decide whether it's worth their while. And instead of treating direct marketing as a pariah industry that needs to be caged or crippled, we reconceive it as an attractive business opportunity for everyone involved.

-- Families get a system that gives them more control -- and an option to be paid for their time.

-- Intermediaries suddenly have a new service to sell. "Sign up with Verizon and choose your own price for receiving promo calls." Just as Verizon makes money by selling its 900 service, it could charge telemarketers to connect calls for a kind of reverse 900 service that compensates the household for listening.

-- But would telemarketers ever be willing to pay for your time? Of course they would, that's what advertising is. A full page print ad in The Wall Street Journal, for instance, costs \$180,000 or 10 cents a reader. Firms are willing to pay dearly for the chance to get their message to you. And telemarketers would pay here only for the targets they reach. If they don't think the person is listening, they can hang up and stop paying. (Consumers are equally free to quit the call and stop getting paid).

Telemarketers with a product that sells and a targeted list would be made better off with a truly free market in compensated calling. Compensation would make people more receptive. Also, regulations now block many forms of marketing. For instance, telemarketers are not allowed to call cell phones, send faxes or use pre-recorded calls (not that this law is universally obeyed). But under a system of compensated calling, it might make more sense to pay you to listen to a recording of James Earl Jones making a sales pitch than to pay a phone-bank caller minimum wage to try to speak to you.

The appropriate role for government is not to tell us what type of calls we can and cannot block. Instead, the "do not call" regulations should simply protect families' right to control whether their phone rings. The current regulation is an important step in this direction. But Congress should allow the market to do more of the work. All that the FTC (or Congress) needs to do is to allow registered households to authorize intermediaries to connect calls that meet their conditions. This can be done by adding 21 words to the current regulation: "A 'specific seller' for purposes of (section) 310.4(b)(1)(iii) shall include intermediaries who are authorized to connect calls that meet pre-specified household prerequisites."

This simple change would strengthen consumers' privacy control and facilitate a true market for telemarketing. You should be able to block any unsolicited calls that don't meet your price and take the ones that do.

Messrs. Ayres and Nalebuff are professors at the Yale Law School and Yale School of Management respectively, and the authors of "Why Not? How to Use Everyday Ingenuity to Solve Problems Big and Small" (Harvard Business School Press, Oct. 24, 2003).

COMPANY

Why not have auto insurance included in the price of gas? This proposal from personal-finance writer Andrew Tobias surely would eliminate uninsured drivers.

Why don't HMOs bundle term life insurance in with their health insurance? That way, the HMO would treat you as if your life really were worth a million dollars.

Why not have a reverse 900 number for telemarketers? Under this scheme you would get paid for each minute that you listen to their pitch. While the telemarketers are trying to sell you a product, you can sell them your time.

Telemarketers make 8 billion calls annually. That's 100 per household. In response to consumer complaints, 20 states now prohibit pitchmen from calling any number registered on the state's "Don't Call" list. The Federal Trade Commission has just proposed creating a national "Don't Call" registry.

One man's problem is another man's business opportunity. Paying people to listen would solve the telemarketers' problem, create a new business and avoid regulation. As things stand, telemarketers are trying to take your time and attention without paying you for it. That's why their success rate is so low, which only leads them to call more often, which makes you like them less, and around it goes.

We could replace the don't-call laws with a simple requirement that telemarketers call only from numbers that have them paying money into the phone account of the person called. Recipients could either name a price per minute or specify that they get no telemarketing calls whatever. Software would make sure that calls went only to people whose prices the marketers were willing to meet.

Creating a privacy market would also allow us to deregulate the telemarketing industry. In a world with household compensation, there's no reason why we would need to restrict prerecorded solicitations. After all, we don't prohibit prerecorded radio or TV ads.

Many businesses would prosper. Companies with legitimate offers wouldn't be caught in the current din. Pollsters would get their surveys answered. Instead of hanging up, people would say: "Are you sure there aren't any more questions?" Just as telephone companies profit from 800 and 900 calls, they could charge a fee for reverse 900 service, too.

Let us make a preemptive strike against skeptics who ask: If ideas like these are so good, why hasn't someone already implemented them? This is a fair question. Not all good new ideas make good stand-alone businesses. Many Why Nots would be best implemented by established firms; an entrepreneur who comes up with a novel mortgage that works will soon enough be swamped by big players who copycat him. In this column we will challenge existing firms to explain why they don't do something differently.

Help us write future columns. Please send us your own Why Not ideas, and tell us what's right or wrong with the proposals we have above. Go to www.forbes.com/whynot.

Ian Ayres is Townsend Professor at Yale Law School and Barry Nalebuff is Steinbach Professor at Yale School of Management.

AT&T launches call-back service
JAPAN: AT&T LAUNCHES NEW CHEAPER CALL-BACK
The Japan Times (XAO) 28 Nov 1996 P.11
Language: ENGLISH

AT&T Communications Services Japan has launched a low- **cost**, flat-rate international **call** -back service in the Tokyo area. The new service is extended to only corporate **customers**. Subscribers can make an

international phone **call** to the United States or Canada at a 50% reduced rate compared to those charged by Japanese international telephone companies. To enjoy the service, corporate subscribers will need to install an AT&T's **autodialer** at a **price** of Y 10,000. But for those that accumulated **calls** worth more than Y 20,000 per month, the **autodialer** comes free of **charge**. The **autodialer** will connect all international **calls** directly through the firm's telecommunication centre in US without any additional procedures. The **call** -back service will be extended to **individual consumers** and to other areas eventually in the near future.

LENDERS CALL FOR STRICTER POLICING
UK - LENDERS CALL FOR STRICTER POLICING
Daily Telegraph (DT) 27 October 1990 p23

At least 6 lenders have been allowed by the Office of Fair Trading to continue trading, despite the latter being given evidence showing that the lenders were making **unsolicited calls** on potential borrowers, which is illegal, according to M Liley, director of the **Consumer Credit Assn**, which represents 1,087 lenders. According to Liley, a loophole in the statutory **rules** also allows some credit brokers to manipulate credit protection insurance in order to **charge** 'extortionate' interest rates. Liley believes that the OFT 'lacks teeth' and should have greater power to act against malpractices more speedily. Meanwhile, Sir G Borrie, Director General of Fair Trading, has said that over 30 mortgage and insurance brokers and estate agents are in danger of losing their licences because of 'improprieties'.

PRIVACY VS. AUTHENTICITY (CRYPTOGRAPHY, INTERNET, COMMERCE, DIGITAL SIGNATURES)

Author: JAKOBSSON, BJORN MARKUS

Degree: PH.D.

Year: 1997

Corporate Source/Institution: UNIVERSITY OF CALIFORNIA, SAN DIEGO (0033)

Chairman: RUSSELL IMPAGLIAZZO

Source: VOLUME 58/08-B OF DISSERTATION ABSTRACTS INTERNATIONAL.

COMMERCE-BUSINESS

Descriptor Codes: 0984; 0405; 0505

In many cryptographic settings, there is a trade-off between privacy and authenticity. We analyze this trade-off in the context of electronic commerce: On one hand, we have schemes whose perfect and un-revokable privacy makes them susceptible to attacks such as blackmail and money-laundry. On the other hand, we have schemes where the authenticity of the funds (in the sense of ownership) is guaranteed by sacrificing user privacy in its entirety. In this work, we propose a model and protocols balancing the needs for privacy against those of authenticity.

In our proposed e-money system, all users enjoy full privacy, but both value of funds and user anonymity can be revoked or suspended unconditionally, by the cooperation of a quorum of banks and consumer rights organizations. Our method employs diffusion of a task into distributed modules; doing so, it enables a stronger and more realistic adversarial setting, and achieves increased security, privacy, availability and functionality without introducing any noticeable disadvantage. The result is a scheme that protects against privacy aided attacks, such as blackmail and money-laundry, as well as the "ultimate crime," where an active attacker gets the bank's secret key or forces the bank to give "unmarked bank notes". Our system, unlike all previous anonymous systems, can prevent all such crimes from successfully being perpetrated, and employs revocation to do so.

One important building block implements the desired balance between privacy and authenticity for digital signatures. We introduce magic ink signatures; such signatures require a quorum of servers to be produced, and a (possibly different) quorum to be unblinded. We present and use an efficient and robust scheme for magic ink DSS signatures.

The mechanisms introduced to balance the need for anonymity against the need to be able to revoke it, together with the notion of challenge semantics that we introduce, provide us with a very versatile system, a second important goal of our investigation. The proposed scheme is efficient and allows for numerous modes of payments.

ABSTRACT

PROBLEM TO BE SOLVED: To provide an anonymous delivery method which cannot be linked in electronic commerce.

SOLUTION: The anonymous delivery/payment method used in connection with electronic commerce is provided. A user starts electronic transaction with a merchant and therefore a specific identifier is supplied to the merchant. For starting respective transactions by the user, the specific identifier supplied to various traders is changed. The merchant attaches the identifier to a label on a package including the commodity which is to be delivered to the user by the reception of the identifier and the package is supplied to the delivery agent being a third person to whom the package is entrusted. The delivery agent accesses a data base for relating the identifier to the address of the specified user. The delivery agent exchanges the label for the label including the name and the address of the user and delivers the package to the user.

Patent Details:

Patent No	Kind	Lan	Pg	Main IPC	Filing Notes
US 6636969	B1		9	G06F-017/60	

Abstract (Basic): US 6636969 B1

NOVELTY - The method involves generating an E-coin comprising a digital signature S and a message m. A hint value mh is generated by a signer by decrypting and blinding the message m, and the value is then stored. Validity of the E-coin is confirmed using the hint value by decrypting the E-coin to create a decrypted version of message md and comparing it with mh value.

USE - Used for conducting electronic commerce between a signer, a receiver and a verifier.

ADVANTAGE - The validity of the E-coin is confirmed without revealing any identifying information about who spend E-coin. The hint value identifies location of record in transcript, thereby reducing the tracing time of the digital signature.

DESCRIPTION OF DRAWING(S) - The drawing shows a flowchart of hint generation process.

Abstract (Basic): US 6529884 B1

NOVELTY - A bank processor (12) receives the merchant and payer public keys, signature of merchant public key from merchant processor (16). The bank processor cancels the account corresponding to payer public key from bank memory (13) and stores new account corresponding to merchant public key, if signature is valid and account corresponding to payer public key is previously stored in bank memory.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

(1) payer device; and

(2) merchant public key signature computing method.

USE - For use in banks.

ADVANTAGE - Since validity of signature of merchant public key is determined, the theft is prevented, thereby improving security.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram of the electronic commerce transaction apparatus.

Abstract (Basic): US 20020133419 A1

NOVELTY - The price of each financial instrument associated with each service or goods sources, is estimated based on bets on future performance of instrument placed by investors. The estimated price is compared with prices of remaining sources, based on which recommendations for each source are defined.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(1) Recommendation generating apparatus; and

(2) Article of manufacture containing recommendation generating programs.

USE - For generating recommendations related to various on-line financial transactions through Internet, wireless network.

ADVANTAGE - Ensures generating secure recommendations due to precise price estimation of financial instruments. Minimizes measurement error and measurement time due to effective characterization of user opinions, thereby accurate recommendations is achieved.

DESCRIPTION OF DRAWING(S) - The figure shows a portion of recommendation interface.

Abstract (Basic): US 20020099670 A1

NOVELTY - A set of user specified access cost information to be
applied to incoming calls, is stored for given user terminals
(104-1-104-M). An amount to charge an originator of the incoming call
is determined partly, based on stored user specified access cost
information.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the
following:

- (1) Call originator access controlling processor based system;
- (2) Call originator access controlling program; and
- (3) Call originator access controlling apparatus.

USE - For controlling access of telemarketers or other call
originators in PSTN or other communication network. Also for other
communication system applications including applications involving
e-mail solicitations over Internet, pages output through paging
networks, and calls, e-mails or pages transmitted through wireless
network.

ADVANTAGE - Reduces the likelihood that a given consumer or user
will receive unwanted calls, while also providing information that can
be used by telemarketers and other call originators to better target
their calls.

DESCRIPTION OF DRAWING(S) - The figure shows a schematic of
communication system implemented with call originator access control
system.

Abstract (Basic): US 20020069181 A1

NOVELTY - A hidden version of signed ciphertext and a request for purchase of given item, are received from the customer (106). The hidden version is decrypted and is returned to the customer, such that the merchant (102) is unable to identify the given item purchased by the customer.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

(1) Processor-based system for controlling access to information items; and

(2) Machine readable medium storing information items access control program.

USE - For controlling access to information items using internet.

ADVANTAGE - The purchase of information items from merchant using internet is implemented so as to ensure privacy of a customer. Also, the amount paid by the customer for particular information item is hidden from payment server and merchant.

DESCRIPTION OF DRAWING(S) - The figure shows the information retrieval system.

Abstract (Basic): WO 200197074 A1

NOVELTY - Several mechanisms are provided for enabling one of the users and one or more entities to control which entities in the distributed data network have access to the information generated in association with the user's activity on the distributed data network. The content to be received by the user is customized in accordance with a portion of accessible information.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (a) Global customization support apparatus;
 - (b) Article of manufacture comprising machine readable medium containing global customization supporting program
- USE - For supporting global customization for performing purchase transaction in distributed data network e.g. Internet

ADVANTAGE - Enables global profiles of each user's behavior to be maintained, so that merchant can customize content for user based on user's activities. Enables each merchant to specify which other merchants can learn the information that it contributes to profiles and/or other desired information.

DESCRIPTION OF DRAWING(S) - The figure shows the block diagram illustrating overview of infrastructure according to global customization support system.

Abstract (Basic): US 6317833 B1

NOVELTY - A voter encrypts a vote with a public key of an authority using a temporary secret to form an encrypted vote. A signature is generated on the encrypted vote using a secret key of the voter. The encrypted vote and the signature are sent to the authority for tallying.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

- (a) Voting method;
 - (b) Vote tallying method
- USE - For elections.

ADVANTAGE - Allows incorrect votes to be easily weeded out. Use of a mix network allows the method to robustly decrypt and permute a vector of encrypted messages, without revealing to voters or the talliers the correspondence between entries in the input and output vectors. The implementation is efficient for large vectors.

DESCRIPTION OF DRAWING(S) - The figure shows a flowchart of the voting process.

Abstract (Basic): US 6157920 A

NOVELTY - A piece of digital cash is transmitted by a first user. A second user evaluates the offer by supplying a bid as input to the offer program. If the bid is indicated as acceptable by the offer program (54), the second user binds the first user to make the corresponding transfer authorized by the digital certificate (52).

DETAILED DESCRIPTION - A piece of digital cash representing an offer by a first user is generated. The piece of digital cash includes a digital certificate and an offer program. The offer program specifies a particular transfer to be made by the first user and authorized by the digital certificate, for a given input. INDEPENDENT CLAIMS are also included for the following:

- (a) Electronic transactions implementing apparatus;
- (b) Electronic transactions implementing program

USE - For electronic transactions carried over computer network and other types of communication media particularly in e-commerce.

ADVANTAGE - Since payment technique is based on any type of transmission mechanism, efficient and practical payment technique is achieved. Since secure transactions are implemented using an instrument referred as executable digital cash or X-cash, X-cash allows an offer to be bound to the corresponding rights to be transferred, thereby enabling the processes of bid searching and payment to be unified. Since trade can be initiated immediately without contacting the originator directly, communication bottlenecks are avoided. Since entitlement authentication, fairness, perfect matchmaking and integrity are provided, X-cash is compact and permit offers and bids to be processed efficiently.

DESCRIPTION OF DRAWING(S) - The figure shows the executable digital cash.

ABSTRACT EP 1150227 A1

Anonymous delivery and payment techniques for use in conjunction with electronic commerce are disclosed. A user, upon entering into an electronic transaction with a merchant, provides the merchant with a unique identifier. For each transaction entered into by this user, the unique identifier provided to various merchants changes. Upon receipt of the identifier, the merchant places the identifier on a label on a package containing the goods to be delivered to the user and provides the package to a trusted third party shipper. The shipper accesses a database to associate the identifier with a particular user's address. The shipper thereafter replaces the label with a label containing the user name and address and delivers the package to the user. Various techniques are disclosed for the generation, storage, and use of the unique identifiers by the user and shipper. Further, an anonymous payment technique may be coupled with the anonymous delivery technique which allow the shipper to authenticate the payment amount agreed to by the user so that the shipper can pay the merchant for the goods and recover the amount paid from the user.

Call originator access control through user-specified pricing mechanism in a communication network

Abstract

Access of telemarketers or other call originators to destination user terminals of a communication system is controlled by storing for a given one of the user terminals a set of user-specified access cost information to be applied to one or more incoming calls directed to the given user terminal. A service provider or associated network processing element of the system utilizes the user-specified access cost information to determine an amount to charge an originator of a given incoming call directed to the user terminal. The charge for the incoming call may thus include a usual toll charge, if any, as well as an additional access cost determined based from the user-specified access cost information for the destination user terminal. The access cost may be presented to the originator of the given incoming call, and the incoming call may be routed to the user terminal only if the presented access cost is approved by the originator of the given incoming call. The access cost is charged to the originator and may be credited at least in part to an account of a called party associated with the user terminal. Advantageously, the invention reduces unwanted calls, while also providing information that allows telemarketers and other call originators to better target their calls.

Inventors: Jakobsson, Bjorn Markus; (*Hoboken, NJ*)**Correspondence** Ryan, Mason & Lewis, LLP**Name and** 90 Forest Avenue**Address:** Locust Valley

Serial No.: 769511**Series Code:** 09**Filed:** January 25, 2001**U.S. Current Class:****705/400****U.S. Class at Publication:****705/400****Intern'l Class:****G06F 017/60**

Claims

What is claimed is:

1. A method for controlling access of call originators to user terminals in a communication system, the method comprising the steps of: storing for a given user terminal of the system a set of user-specified access cost information to be applied to one or more incoming calls directed to the user terminal; and determining an amount to charge an originator of a given incoming call directed to the user terminal based at least in part on an access cost for the given incoming call as determined from the user-specified access cost information.
2. The method of claim 1 wherein the access cost is presented to the originator of the given incoming call and the incoming call is routed to the user terminal only if the presented access cost is approved by the originator of the given incoming call.
3. The method of claim 1 wherein the access cost is charged to the originator and credited at least in part to an account of a called party associated with the user terminal.
4. The method of claim 1 wherein the user terminal comprises a telephone.
5. The method of claim 1 wherein the user terminal comprises a computer.
6. The method of claim 1 wherein the user terminal comprises a personal digital assistant.
7. The method of claim 1 wherein the set of user-specified access cost information comprises one or more access rules specified by the user and indicating a particular access cost for an incoming call under one or more specified conditions.
8. The method of claim 1 wherein the set of user-specified cost information is stored in a database associated with a service provider that implements the determining step.
9. The method of claim 1 wherein the set of user-specified cost information is stored in a database associated with the user terminal.
10. The method of claim 1 wherein the originator of the given incoming call comprises a telemarketer.
11. The method of claim 1 wherein a user associated with the terminal is permitted to waive the access cost for the given incoming call.
12. The method of claim 11 wherein the waiver of the access cost is in response to an offer from the call originator made after the incoming call is routed to and accepted at the user terminal.
13. The method of claim 1 wherein the set of user-specified access control information comprises at least one of a caller-specific access cost and a caller-specific access rule associated with an identifier of a particular call originator.
14. The method of claim 1 wherein the set of user-specified access control information comprises at least one of a general access cost and a general access rule to be applied to a plurality of incoming calls regardless of the particular call originator associated therewith.
15. The method of claim 1 wherein the user-specified access cost information is at least in part entered by the user at the user terminal via a menu-driven user interface.

17. A processor-based system for controlling access of call originators to user terminals in a communication system, the system comprising: one or more processing elements configured to store for a given user terminal of the system a set of user-specified access cost information to be applied to one or more incoming calls directed to the user terminal, and to determine an amount to charge an originator of a given incoming call directed to the user terminal based at least in part on an access cost for the given incoming call as determined from the user-specified access cost information.

18. A machine-readable medium containing one or more software programs for controlling access of call originators to user terminals in a communication system, wherein the one or more programs when executed implement the steps of: storing for a given user terminal of the system a set of user-specified access cost information to be applied to one or more incoming calls directed to the user terminal; and determining an amount to charge an originator of a given incoming call directed to the user terminal based at least in part on an access cost for the given incoming call as determined from the user-specified access cost information.

19. An apparatus for use in controlling access of call originators to user terminals in a communication system, the apparatus comprising: a memory for storing for a given user terminal of the system a set of user-specified access cost information to be applied to one or more incoming calls directed to the user terminal; and a processor coupled to the memory and operative to determine an amount to charge an originator of a given incoming call directed to the user terminal based at least in part on an access cost for the given incoming call as determined from the user-specified access cost information.

FIELD OF THE INVENTION

BACKGROUND OF THE INVENTION

[0003] A number of known techniques address the issue of controlling access of telemarketers to consumers over a network. One such technique involves selective call blocking. In this technique, a consumer is able to specify that only those incoming calls corresponding to designated originating telephone numbers will generate a ring at the destination terminal. More particularly, the consumer can create a database of known telephone numbers, e.g., those of family members, friends, cell phones, car phones, work places, schools, etc., and a central office or other processing element of the network is configured to process incoming calls directed to the

consumer such that only calls from the designated numbers will get through to the destination terminal. However, these and other existing techniques for controlling access telemarketers have been unable to provide adequate protection against the above-noted problem of excessive telemarketing activity.

[0004] A need therefore exists in the art for improved techniques for controlling access of telemarketers to consumers. It is particularly desirable that such techniques ensure that telemarketers are more likely to reach consumers that are interested in a particular type of offer, while also protecting consumers against excessive telemarketing activity.

SUMMARY OF THE INVENTION

[0005] The invention provides improved techniques for controlling access of telemarketers or other types of call originators to user terminals of a communication system.

[0006] In accordance with one aspect of the invention, one or more elements of the system store a set of user-specified access cost information to be applied to one or more incoming calls directed to a corresponding telephone, computer, personal digital assistant or other user terminal. A service provider or associated network processing element of the system utilizes the user-specified access cost information to determine an amount to charge an originator of a given incoming call directed to the user terminal. The charge for the incoming call may thus include a usual toll charge, if any, as well as an additional access cost determined based from the user-specified access cost information for the destination user terminal. The access cost may be presented to the originator of the given incoming call, and the incoming call may be routed to the user terminal only if the presented access cost is approved by the originator of the given incoming call. The access cost is charged to the call originator and is preferably credited at least in part to an account of a called party associated with the user terminal.

[0007] The present invention may thus be configured in an illustrative embodiment so as to allow an access cost established by a called party to be presented to a caller before the call is routed through to the called party, and to allow the called party to benefit by receiving at least a portion of the access cost as paid by the caller. As noted above, the access cost for a given call is determined based on the access cost information for the destination terminal of the call as specified by the called party associated with that terminal.

[0008] In accordance with another aspect of the invention, the set of user-specified access cost information may include one or more access rules specified by the user and indicating a particular access cost for an incoming call under one or more specified conditions. As another example, the set of user-specified access control information may include one or more caller-specific access costs or caller-specific access rules associated with an identifier of a particular call originator. The set of user-specified access control information may also include one or more general access costs and general access rules to be applied to a number of incoming calls regardless of the particular call originator associated therewith. The user-specified access cost information may be entered at least in part by the user at the user terminal via a menu-driven user interface. As another example, the menu-driven user interface may be implemented at a web site of the service provider. The user-specified cost information may be stored in a centralized manner, e.g., in a database associated with the service provider, or in a distributed manner, e.g., in a database or other type of memory associated with the user terminal.

[0009] In accordance with a further aspect of the invention, the user associated with the user terminal is permitted to waive the access cost for the given incoming call, e.g., during or after the call if the call turns out to be of interest to the user. The waiver of the access cost may be in response to an offer from the call originator made after the incoming call is routed to and accepted at the user terminal.

[0010] Advantageously, the invention reduces the likelihood that a given consumer or other user will receive unwanted calls, while also providing information that can be used by telemarketers and other call originators to better target their calls.

BRIEF DESCRIPTION OF THE DRAWINGS

[0014] FIG. 4 is a flow diagram of an example access control process in accordance with the invention as implemented in the illustrative system of FIG. 1.

DETAILED DESCRIPTION OF THE INVENTION

[0019] Although shown as being separate from the network 106 in FIG. 1, the service provider 108 may represent an element of the network, such as a network processing element of the network 106, or may represent

a provider of all or a portion of the network 106. For example, the service provider 108 may be a telecommunication network operator, an Internet service provider, or any other provider of a communication service over a network.

[0020] A given one of the user terminals 104-j may represent a conventional telephone, a desktop or portable personal computer, a mobile telephone, a PDA, a television set-top box or any other type of device capable of retrieving telemarketing information over network 106.

[0021] It should be understood that although only a single service provider 108 and particular numbers of telemarketers 102 and user terminals 104 are shown in the FIG. 1 embodiment, the invention is more generally applicable to any number, type and arrangement of different service providers, telemarketers and user terminals.

[0022] FIG. 2 shows one possible implementation of a given one of the processing elements of system 100. The implementation in FIG. 2 may represent one or more of the elements 102, 104 and 108, or portions of these elements. In this example implementation, the element of system 100 includes a processor 200, an electronic memory 220, a disk-based memory 240, and a network interface 260, all of which communicate over a bus 270. One or more of the processing elements of system 100 may thus be implemented as a personal computer, a mainframe computer, a computer workstation, an intelligent telecommunication switch, or any other type of digital data processor as well as various portions or combinations thereof. The processor 200 may represent a microprocessor, a central processing unit, a digital signal processor, an application-specific integrated circuit (ASIC), or other suitable processing circuitry. It should be emphasized that the implementation shown in FIG. 2 is simplified for clarity of illustration, and may include additional elements not shown in the figure. In addition, other arrangements of processing elements may be used to implement one or more of the elements of the system 100.

[0023] The elements 104 and 108 of system 100 execute software programs in accordance with the invention in order to provide telemarketing access control in a manner to be described in detail below. The invention may be embodied in whole or in part in one or more software programs stored in one or more of the element memories, or in one or more programs stored on other machine-readable media associated with the elements of the system 100.

[0024] In accordance with the present invention, the system 100 is configured such that users are permitted to specify access control information that controls the access of telemarketers to the corresponding user terminals. For example, in an implementation of system 100 in which network 106 represents a PSTN and service provider 108 is a central office or other network processing element associated with the PSTN, a user associated with a given terminal 104-j may specify access costs that control the manner in which one or more of the telemarketers 102 can direct calls to the given terminal. The invention includes a user interface that allows users to specify access control information in the form of access costs for particular call originators as well as general access rules that govern all incoming calls. It should be noted that call originators are also referred to herein as simply "callers."

[0025] An access cost determined in accordance with the invention is preferably charged to the originator and credited at least in part to an account of a called party associated with the user terminal.

[0026] The present invention thus allows an access cost established by a called party to be presented to a caller before the call is routed through to the called party. As will be described in greater detail below, the access cost for a given call is determined based on the access cost information for the destination terminal of the call. This access cost information may be specified by the called party associated with the destination terminal.

[0027] The invention will be further described in conjunction with FIGS. 3 and 4 with reference to a particular implementation of FIG. 1 involving telephone calls delivered over a PSTN to a user terminal. Other possible implementations involving other types of networks and other types of calls will be readily apparent to those skilled in the art and will not be described in detail herein.

[0029] The first portion 306 of the entry 304-1 includes a set of K call originating numbers and for each of the K originating numbers one or more corresponding user-specified access costs. The access costs for a given one of the K numbers may include a single cost to be used in all situations when an incoming call from that number directed to the user terminal is received by the service provider. Alternatively, a set of different costs may be specified for one or more of the K numbers, including, e.g., different costs for use at different times of day or under other specified circumstances. The different costs can be applied in accordance with general user-specified access rules to be described below.

[0031] 1. If the caller identifier (ID) of a given incoming call is not revealed, the access cost is \$2.00.

[0033] 3. If the incoming call originates from one of a specified list of area codes, the access cost is \$0.15.

[0035] 5. If the incoming call is identified as being from one of a specified list of numbers recently called by a user, the access cost is \$0.

[0037] In accordance with the invention, the user-specified access costs applicable to a given incoming call are generally added to the cost of the call as billed to the call originator. Advantageously, this approach not only limits telemarketing activity by forcing telemarketers to better target their calls, it also allows users to provide useful feedback to telemarketers regarding which calls the users would be inclined to accept in the future.

[0039] The access costs can also be modified by the user during or after a given call, using the above-noted user interface. For example, the user may remain on the line after completion of a call, call another designated telephone number or visit a password-protected web site provided by the service provider, and then enter commands to direct that the most recent call originator be moved from one charging category to another. As another example, this modification of access costs may be implemented via an automated menu-driven process, provided to the user via the user terminal, at or near the completion of the call.

<http://appft1.uspto.gov/netacgi/nph-Parser?Sect1=PTO2&Sect2=HITOFF&p=1&u=%2Fnetahml%2...> 12/6/04

The user interface may be provided at a corresponding user terminal 104-j, or at another terminal capable of interacting with the service provider 108. In step 402, an incoming call directed to the user terminal 104-j is received in a network processing element associated with the service provider 108. User-specified access control information for the given user is then retrieved and the relevant rule or rules are applied, as indicated in step 404. As noted in conjunction with FIG. 3, the user-specified access control information may include either caller-specific costs or general access rules or both. For the caller-specific costs, the particular call originator or originating number may be determined using conventional techniques such as caller ID, automatic number identification (ANI), or other similar techniques. The operation of such techniques is well understood in the art and therefore not further described herein.

[0041] Application of the relevant general access rules in conjunction with any caller-specific access cost yields an access cost for the incoming call. This access cost is typically a cost that is paid by the call originator in addition to the usual toll charges for the call. In step 406, a determination is made as to whether the determined access cost is greater than zero. If the access cost is greater than zero, the cost is presented to the call originator for approval in step 408. This step may be implemented in a manner similar to that used in conjunction with conventional collect calling, i.e., via a human or automated operator getting on the line and asking if the caller will accept responsibility for paying the user-specified access cost. Other techniques may also be used, e.g., the access cost may be displayed on a terminal of a telemarketer that originated the incoming call. As another example, a given telemarketer or other call originator may establish a policy with the service provider that all access costs below a specified threshold are to be automatically deemed accepted by that call originator. In the latter example, the service provider need not present access costs that are below the specified threshold to the call originator.

[0042] If the access cost is not accepted by the call originator in step 410, the call is terminated in step 412 instead of being routed to the destination user terminal, and the process returns to step 402 to await the next incoming call directed to the given user terminal. If the access cost is accepted by the call originator in step 410, or if the access cost is determined to be zero in step 406, the incoming call is routed to the destination user terminal in step 414.

[0043] As noted previously, the access cost can be waived by the user during or after the call, e.g., via entry of designated commands. This is indicated in step 416, which determines if the user has waived the access cost. The user may waive the access cost if the call is actually of interest to the user, or in response to special offers made by the telemarketer during the call. For example, a telemarketer may offer the user a certain discount on a product or service in exchange for the user waiving the access cost. If the user does not waive the access cost in step 416, the call originator is billed for the usual toll charges, if any, as well as the access cost, as indicated in step 418, and the process returns to step 402 to await the next incoming call directed to the given user terminal. If the user does waive the access cost in step 420, the call originator is billed for the call without regard to the access cost, i.e., is billed only the usual toll charges for the call, if any, and the process then returns to step 402 to await the next incoming call.

[0044] In accordance with the invention, the access cost for a given call as determined in the manner illustrated in FIG. 4 may be credited in whole or in part to an account of the user that is the target of the call. For example, the user may have an account with the service provider in which at least a portion of the access cost appears as a credit to offset other charges, e.g., outgoing calls made by that user under the same account. Of course, some or all of the access cost may be retained by the service provider to offset the costs associated with providing the service.

[0045] The telemarketing access control process described above can thus be offered as a service by the service provider 108 to users of the system 100. The service may be offered to the users free of charge, with the service provider paying for the service through the billing of user-specified access costs to callers. As noted above, the service provider 108 may also provide part of the access cost profits back to the users, e.g., as credits on their own telephone bills. As other examples, the service can be provided for a fixed monthly fee, or a flat fee per call. The access control service can employ particular area codes or exchange codes to identify the user terminals that service, or can allow any telephone number to be associated with the service. Advantageously,

this type of service may be implemented in an existing PSTN, without requiring any modification to existing telephones. It may also be implemented in newly-developed user terminals, e.g., in web-enabled wireless telephones or PDAs, through appropriate software modules, attachments, etc.

[0046] It should be noted that the invention does not require per-call billing. For example, the service provider may bill access costs and other charges in accordance with a service plan based on, e.g., flat monthly or weekly charges.

[0047] One or more databases having entries of the type shown in FIG. 3 may be used to implement the access control process. These one or more databases may be centralized at the service provider 108, or alternatively may be distributed over multiple network elements or user terminals. For example, the portions of the database (s) for particular user terminals can be located in the central office or other network processing element associated with those user terminals. As another example, the database entry for a particular user may be stored on the corresponding user terminal, and the database entry accessed by the service provider prior to or during call setup. In addition, the service provider 108 need not be "on-line" at all times with the network 106, i.e., need not be continuously connected to the network 106. For example, the service provider may be presented by the call originator with digital signatures that have been given to the call originator by certain users, the digital signatures indicating that the call originator has agreed to pay user-specified access costs to obtain telemarketing access to the users. This type of implementation allows the service provider to operate in an at least partially off-line mode relative to the network 106.

[0048] As noted previously, a significant advantage of the present invention is that it discourages unwanted telemarketing calls. However, the invention also allows the service provider to inform the telemarketers regarding the types of calls that particular users want to receive, as indicated by low or waived access costs for certain incoming calls. This gives telemarketers an advantage in determining what users are interested in their goods or services. For example, users can specify low or waived access costs for calls from known home mortgage telemarketers, which indicates that the user generally wants to be contacted regarding home mortgages. This "call invitation" aspect of the invention can be used by telemarketers to create improved user profiles and to increase the precision with which they target calls. The user can also use the access costs to specify what times of the day he or she is the most willing to be called, which is another piece of user preference information that is of value to telemarketers. The service provider can increase its profits by selling such information to the telemarketers, preferably with the consent of the users.

[0049] It should be understood that the above-described embodiments of the invention are illustrative only. For example, the invention can be applied to a wide variety of different types of communication systems, networks, service providers, telemarketers and user terminals. In addition, although illustrated in the context of telemarketing applications, the invention is also applicable to controlling access of other types of call originators. Furthermore, the particular access control process utilized in a given embodiment may vary depending upon factors such as the pricing mechanisms used, the type of network and service provider, and the type of user interface through which access costs are specified by the system users. These and numerous other alternative embodiments within the scope of the following claims will be apparent to those skilled in the art.
